The loop one institute ran once becomes a tool any laboratory can run and keep

A. What scBaseCount showed

An agent finds and annotates SRA experiments; a fixed pipeline reprocesses them: 502 million cells, one assay. Built once by one institute on a cloud platform, and offered as a blueprint rather than a tool.

B1. A laboratory that already holds the data

A curated table that wants search, browse and download pages, hosted without a server to keep up. Today: a framework, templates, a host, and the student who built the site.

B2. A laboratory that still has to collect

Every public dataset on its tissue, organism or perturbation, processed with its own tools. Today: a search, a spreadsheet, a fetcher, a workflow manager, a cluster account, and a person.

C. DataBaseAgent: two kinds of project, one tool

One binary on a laptop; nothing to deploy.

Static: publish what you have.
A SKILL template shapes the table into a one-file site; the assistant publishes it to GitHub Pages or Cloudflare Pages through the provider's MCP server.

Collecting: collect what you need.
Free-text criteria; any assay; any shell steps; jobs on the laboratory's own server, outliving the laptop.

Agents act only through validated, recorded commands; every decision carries a reason and an author; agents run only when asked.

Locked versions, snapshots, manifests and checksums keep the repository maintainable after it is built.

Design contribution; usability not yet evaluated.
